METHOD AND APPARATUS FOR ELECTRONIC COLLATION

FIELD OF THE INVENTION

This invention relates generally to the production of multiple copies of a document, and more particularly to electronic collation.

BACKGROUND OF THE INVENTION

Collation is the process of sorting pages of multiple copies of a document so that the pages of each copy are contiguous and ordered (i.e. all the pages of copy one are contiguous, all the pages of copy two are contiguous, and so on). Traditionally, collation has been performed mechanically using output bins or original re-feeding. In the former case, as each page of the original is copied, each copy is placed in a different bin. When the required number of copies of a page has been made or the number of available bins has been exhausted, the next page is copied in a similar fashion. This process is continued until all pages have been copied. Mechanical output bin collation suffers from a number of limitations. First, the number of collated copies that can be printed cannot exceed the number of bins available. Second, the number of pages in a single copy cannot exceed the capacity of an output bin.

The mechanical limitations associated with the use of sorting bins can be overcome by re-feeding the original pages once for each copy. Using this technique, collated copies are stacked upon each other in a single output bin. Although this technique avoids the problems associated with the use of multiple output bins, it introduces another serious shortcoming: performance. Each page of the original must be fed into the hardcopy device multiple times. This process requires extra time and introduces additional potential for mechanical failure. In contrast, when using output bins to collate, it is only necessary to feed each page of the original once, thus reducing the potential for mechanical failure and avoiding the time required to repeatedly feed the original pages.

Printers, being digital hardcopy devices, can also take advantage of digital collation. Unlike copiers, printers receive the original already in digital form. Typically, this digital form is translated within the printer into another digital form referred to as "print ready." When in print ready form, original pages can be retrieved and printed at a speed that at least matches that of the print engine. In order to produce collated copies, printers will record the print ready form of the original into storage for subsequent use. Similar to copiers, as each copy is produced, the print ready form of the pages of the original are digitally re-fed by retrieving them from storage; the print ready digital form of each original page is used to produce a printout of that original page.

Digital collation works well, provided the digital hardcopy device has adequate digital storage. If the amount of storage is not adequate to store all of the original pages in print ready form, digital collation fails. Rather than faithfully printing the number of collated copies requested, only a single copy is typically printed; it is not possible to print additional copies because it is not possible to store the original in its entirety.

1 With hardcopy devices that utilize disk drives to store the original pages in digital form,
2 exhausting the amount of available storage is rare. However, very few hardcopy devices (less
3 than 10%) have a hard disk installed. For the majority of printers (e.g., the HEWLETT-
4 PACKARD (TM) LASERJET (TM) model 4050 printer), digital collation is performed using
5 RAM storage. Because of the relatively high cost of RAM per megabyte in comparison to
6 hard disk storage, the amount of storage that is provided through RAM is severely limited.
7 This drastically increases the chances that available storage will be exhausted when using
8 digital collation to print.

9
10 When available storage is exhausted during a digital collation operation, there is
11 currently no reliable way to recover or to even notify the end-user who originated the print
12 job. This means, for example, that if a reasonably large document is printed using digital
13 collation, only a single copy of the document will print—without warning or explanation that
14 the additional copies did not print.

15 16 SUMMARY OF THE INVENTION

17
18 In one respect, the invention is a method for printing N collated copies of a document
19 on a printer, where N is an integer greater than one. The method determines whether the
20 printer has sufficient capacity to print N collated copies of the document. If the printer has
21 insufficient capacity to store one copy of the document, then the method performs the
22 following step N times: sending a single copy of the document to the printer. The capacity
23 may be memory to store one copy of the document in print ready form.

24
25 In another respect, the invention is a computer readable medium on which is
26 embedded a program that performs the method described above.

27
28 In yet another respect, the invention is an apparatus for processing an incoming print
29 job requesting N collated copies of a document on a printer, where N is an integer greater
30 than one. The apparatus comprises a memory, a spooler connected to the memory, a status

1 agent and a control logic connected to the spooler and the status agent. The memory is
2 configured to store the document. The spooler is configured to send an outgoing print job to
3 the printer. The status agent is configured to receive from the printer information regarding
4 whether the printer has sufficient capacity to collate the document. The control logic controls
5 the spooler on the basis of this information.

6
7 In comparison to known prior art, certain embodiments of the invention are capable of
8 achieving certain advantages, including some or all of the following: (1) printing of the
9 correct number of copies in almost all cases transparently to the user; (2) automatic detection
10 of and compensation for limitations due to inadequate storage capacity; and (3) relaxation of
11 device memory requirements, allowing, for example, production of printers with less
12 expensive RAM memory without sacrificing digital collation performance. Those skilled in
13 the art will appreciate these and other advantages and benefits of various embodiments of the
14 invention upon reading the following detailed description of a preferred embodiment with
15 reference to the below-listed drawings.

16 17 BRIEF DESCRIPTION OF THE DRAWINGS

18
19 Figure 1 is an interaction diagram of devices and their actions, according to one
20 embodiment of the invention;

21 Figure 2 is a flowchart of a method according to an embodiment of the invention; and

22 Figure 3 is a block diagram of component modules according to one embodiment of
23 the invention.

24 25 DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

26
27 Figure 1 is an interaction diagram of a system 100 comprising a printer 110 and a
28 computer system 120 as well as object flow between them, according to one embodiment of
29 the invention. The printer 110 is capable of performing digital collation and includes a
30 memory 130 for this purpose. The memory 130 may be RAM, but this need not be the case.

1 The memory 130 may be shared with other print functions. The system 100 facilitates digital
2 collation whenever the capacity of the memory 130 is overrun, regardless of the nature or
3 type of the memory 130. The printer 110 may contain other memories for other purposes
4 (e.g., buffers for incoming print jobs, resident program memory, font memory, etc.); the
5 memory 130 typically stores the a document for collation in print ready form. The computer
6 system 120 includes a memory 140 that is typically much larger than the memory 130 in the
7 printer 110. When the size of a document for printing is too large to fit in the memory 130,
8 the document can still be printed with collation by storing the document in the memory 140,
9 as described in greater detail below.

10
11 Figure 1 depicts the print job 150 originating from a source (notshown) and going to
12 both the printer 110 and the computer system 120. The print job 150 comprises a document
13 as well as an instruction for N-wise collation (i.e., N collated copies of the document). In
14 most embodiments, the document in the print job 150 is not in print ready form, although that
15 need not be the case; in those embodiments, the computer system 120 and/or the printer 110
16 may convert the document to print ready form. Although not depicted as such, the originator
17 of the print job 150 can be the computer system 120 itself. In yet another alternative, the
18 print job 150 may pass through the computer system 120 before reaching the printer 110; in
19 other words, the print job 150 may pass serially to the computer system 120 then the printer
20 110, rather than in parallel, as shown. The computer system 120 may be a print server on a
21 computer network.

22
23 The object flow in Figure 1 will now be described. First, the computer system 120
24 and the printer 110 receive the print job 150 with a collation copy count of N. The computer
25 system 120 stores a copy of the document in its memory 140. The printer begins printing
26 copy 1 of the document while storing a copy of the document in its memory 130 for later
27 digital re-feeding after copy 1 concludes printing. If the memory 130 is inadequate to store
28 the document, then an indication of storage exhaustion 160 is transmitted from the printer 110
29 to the computer system 120. Upon receipt of the indication of storage exhaustion 160, the

1 computer system 120 sends the document to the printer 110 N-1 times, each one as a single
2 copy print job.

3
4 Figure 2 is a flowchart of a method 200 according to an embodiment of the invention.
5 The method 200 is typically performed by the computer system 120. The method 200 begins
6 when an N-collation print job (i.e., a job requesting N collated copies of a document to be
7 produced on a destination printer (e.g., the printer 110)) is received (210). The print job is
8 then stored (220). Next, the method 200 tests (230) whether the printer 110 has sufficient
9 memory for collation of the job. Typically, sufficient memory is that required to store one
10 copy of the document in print ready form. If the printer 110 has sufficient memory, the
11 method 200 terminates after the testing step 230. On the other hand, if the printer's (110)
12 memory is insufficient, then the method 200 modifies (240) the print job by overwriting the
13 copy count to be one and proceeds to print N-1 single copies of the document, assuming that
14 the printer 110 has already received the original print job and will produce one copy of the
15 document as a result.

16
17 To produce the extra N-1 single copies of the document, the method 200 initializes
18 (250) a counter variable to be two. The method 200 then repeats a loop by sending (260) the
19 modified job to the printer 110, incrementing (270) the counter variable and testing (280)
20 whether the counter variable equals N, in which case the method 200 terminates.

21
22 The testing step 230 for determining whether the printer's memory is sufficient will
23 now be described in greater detail. According to one implementation, the printer 110
24 affirmatively reports that it's memory is sufficient. According to another implementation, the
25 computer system 120 waits for the printer 110 to report that its memory is insufficient. While
26 awaiting this bad news, the computer system 120 checks whether the first copy of the
27 document has completed printing. If the first copy has completed printing and the printer has
28 not yet reported that its memory is insufficient, then the printer very likely has adequate
29 storage capacity and the computer system 120 so concludes. The computer system 120 can
30 prompt the printer 110 to report on its memory status in a variety of ways. According to one

09723600-120100

technique, the computer system 120 polls the printer by querying a PML (print management language) or SNMP (simple network management protocol) object, depending upon the nature of the connection between the printer 110 and the computer system 120. PML is a protocol for communicating with directly connected (e.g., parallel or serial) peripherals, as opposed to networked peripherals. PML is similar to SNMP, which is used with network connected devices instead.

Another technique for prompting the printer 110 to report its memory status is described in commonly assigned U.S. patent application serial number 09/393,215, entitled "Method and Apparatus for Establishing Two-Way Communication with a Remote Printer," filed September 9, 1999, which is hereby incorporated by reference. According to this technique, the computer system 120 sends to the printer 110 a print job, in which is embedded a modified PDL (print job language) SOCKETPING command directing the printer to send job status information to a specific network address.

Although the testing step 230 preferably determines whether the printer 110 has adequate storage capacity to perform digital collation, the testing step 230 can alternatively or additionally check for other capacity inadequacies (e.g., processing power, other hardware deficiencies, or the presence of a digital collation feature at all). In other words, the testing step 230 can generally determine adequate capacity in a broad sense, not just storage capacity.

Figure 3 is a block diagram of pertinent component modules within the computer system 120, according to one embodiment of the invention. The pertinent component modules include a reception port 310, the memory 140, a spooler 320, a control logic 330 and a status agent 340. The reception port 310 performs the receiving step 210, receiving an incoming print job. Of course, the reception port 310 and the receiving step 210 are not present when the print job originates at the computer system 120. The memory 140 stores the print job, as already described. The spooler 320 sends any print jobs to the printer 110. The spooler 320 can forward the original print job to the printer 110 if necessary, as would be the case when, unlike the case shown in Figure 1, the original print job is not independently sent

1 to the printer 110 along a parallel path. The spooler 320 also sends modified jobs to the
2 printer 110 as needed. The status agent 340 performs the testing step 230 to determine
3 memory status of the printer 110. The control logic 330 controls and coordinates the
4 operation of the other components. For example, the control logic 330 may perform the
5 modification step 240, the initialization step 250, the sending step 260, the incrementing step
6 270 and the testing step 280.

7
8 The spooler 320 and the status agent 340 are preferably subprograms called by the
9 control logic 330, which can be a main program. Alternatively, the spooler 320 and the status
10 agent 340 can be integrated into the control logic 330. Other integration and rearrangements
11 of functionality are possible, as one skilled in the art would appreciate. Although software is
12 preferred, some or all of the spooler 320, the control logic 330 and the status agent 340 could
13 be hardware or firmware modules. Furthermore, the method 200, apart from any particular
14 architecture such as the one shown in Figure 3, can be implemented by program modules,
15 whether software, firmware, hardware or some combination. Software modules can exist in a
16 variety of forms both active and inactive, including source code, object code, executable code
17 or other formats. Hardware modules can take the form of physical devices or hardware
18 description language (HDL) files. Software files or HDL files can be embodied on a
19 computer readable medium, which include storage devices and signals, in compressed or
20 uncompressed form. Exemplary computer readable storage devices include conventional
21 computer system RAM, ROM (read only memory), EPROM (erasable, programmable ROM),
22 EEPROM (electrically erasable, programmable ROM), and magnetic or optical disks or tapes.
23 Exemplary computer readable signals, whether modulated using a carrier or not, are signals
24 that a computer system can be configured to access, including signals downloaded through
25 the Internet or other networks. In a sense, the Internet itself, as an abstract entity, is a
26 computer readable medium. The same is true of computer networks in general.

27
28 What has been described and illustrated herein is a preferred embodiment of the
29 invention along with some of its variations. The terms, descriptions and figures used herein
30 are set forth by way of illustration only and are not meant as limitations. Those skilled in the
